

Bonus Question

A mandate to reach net-zero emissions "as fast as possible" fundamentally shifts global economics, subordinating traditional shareholder value to mandatory, immediate carbon offsetting. Under this strict timeline, every company will be forced to fully internalize the cost of their emissions. This leaves only two viable investment categories: mega-caps profitable enough to absorb these massive new costs (such as Apple), and the carbon capture companies providing the actual offsets.

While highly profitable giants will survive the transition, the financially optimal strategy is to allocate the entire \$1 billion fund directly into carbon capture enterprises. Because it is practically impossible for the global economy to organically reduce all emissions to zero in the near term, the world will have to rely heavily on direct carbon removal. Since these carbon capture companies are currently small, deploying our capital now allows us to enter at highly reasonable valuations just before their technology becomes a mandatory global necessity.
